Pointers in C

Introduction

- A pointer is a variable that represents the location (rather than the value) of a data item.
- They have a number of useful applications.
  - Enables us to access a variable that is defined outside the function.
  - Can be used to pass information back and forth between a function and its reference point.
  - More efficient in handling data tables.
  - Reduces the length and complexity of a program.
  - Sometimes also increases the execution speed.

Basic Concept

- In memory, every stored data item occupies one or more contiguous memory cells (bytes).
  - The number of bytes required to store a data item depends on its type (char, int, float, double, etc.).
- Whenever we declare a variable, the system allocates memory location(s) to hold the value of the variable.
  - Since every byte in memory has a unique address, this location will also have its own (unique) address.

Contd.

- **Consider the statement**

```
int   xyz = 50;
```

  - This statement instructs the compiler to allocate a location for the integer variable `xyz`, and put the value `50` in that location.
  - Suppose that the address location chosen is `1380`.

xyz	→	variable
50	→	value
1380	→	address

Contd.

- During execution of the program, the system always associates the name `xyz` with the address `1380`.
  - The value `50` can be accessed by using either the name `xyz` or the address `1380`.
- Since memory addresses are simply numbers, they can be assigned to some variables which can be stored in memory.
  - Such variables that hold memory addresses are called *pointers*.
  - Since a pointer is a variable, its value is also stored in some memory location.

Contd.

- Suppose we assign the address of `xyz` to a "pointer" variable `p`.
  - `p` is said to point to the variable `xyz`.

Variable	Value	Address
xyz	50	1380
p	1380	2545

```
p = &xyz;
```

Accessing the Address of a Variable

- The address of a variable can be determined using the '&' operator.
  - The operator '&' immediately preceding a variable returns the *address* of the variable.
- Example:

```
p = &xyz;
```

  - The *address* of xyz (1380) is assigned to p.
- The '&' operator can be used only with a *simple variable* or an *array element*.

```
&distance
&x[0]
&x[i-2]
```

Contd.

- **Following usages are illegal:**

```
&235                    -- Pointing at a constant.

int   arr[20];
  :
&arr;                   -- Pointing at array name.

&(a+b)                  -- Pointing at expression.
```

Example

```
#include  <stdio.h>
main()
{
    int   a;
    float  b, c;
    double  d;
    char  ch;

    a = 10;   b = 2.5;  c = 12.36;  d = 12345.66;  ch = 'A';
    printf  ("%d is stored in location %u \n",  a,  &a) ;
    printf  ("%f is stored in location %u \n",  b,  &b) ;
    printf  ("%f is stored in location %u \n",  c,  &c) ;
    printf  ("%ld is stored in location %u \n", d,  &d) ;
    printf  ("%c is stored in location %u \n",  ch, &ch) ;
}
```

Output:

```
10 is stored in location 3221224908
2.500000 is stored in location 3221224904
12.360000 is stored in location 3221224900
12345.660000 is stored in location 3221224892
A is stored in location 3221224891
```

Pointer Declarations

- Pointer variables must be declared before we use them.
- General form:

```
data_type *pointer_name;
```

- Three things are specified in the above declaration:
  - The asterisk (*) tells that the variable `pointer_name` is a pointer variable.
  - `pointer_name` needs a memory location.
  - `pointer_name` points to a variable of type `data_type`.

Contd.

- **Example:**

```
int  *count;
float *speed;
```

- **Once a pointer variable has been declared, it can be made to point to a variable using an assignment statement like:**

```
int *p, xyz;
 :
p = &xyz;
```

  - **This is called *pointer initialization*.**

Things to Remember

- Pointer variables must always point to a data item of the *same type*.

```
float   x;
int    *p;
:
p = &x;
```

➔ will result in erroneous output

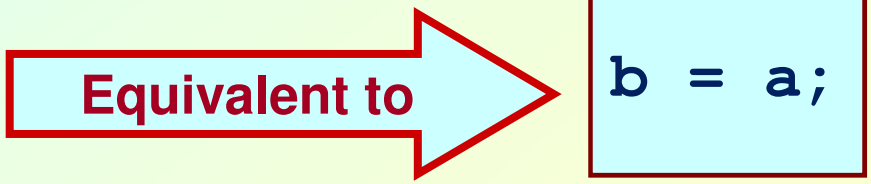
- Assigning an absolute address to a pointer variable is prohibited.

```
int   *count;
:
count = 1268;
```

Accessing a Variable Through its Pointer

- Once a pointer has been assigned the *address* of a variable, the *value* of the variable can be accessed using the *indirection operator* (*).

```
int   a, b;
int   *p;
:
p = &a;
b = *p;
```



Example 1

```
#include  <stdio.h>
main()
{
    int   a, b;
    int   c = 5;
    int   *p;

    a  =  4  *  (c  +  5) ;

    p  =  &c;
    b  =  4  *  (*p  +  5) ;
    printf  ("a=%d  b=%d \n",  a, b);
}
```

Equivalent

```
a=40 b=40
```

Example 2

```
#include  <stdio.h>
main()
{
    int  x, y;
    int  *ptr;

    x = 10 ;
    ptr = &x ;
    y = *ptr ;
    printf (”%d is stored in location %u \n”,  x,  &x) ;
    printf (”%d is stored in location %u \n”,  *&x,  &x) ;
    printf (”%d is stored in location %u \n”,  *ptr,  ptr) ;
    printf (“%d is stored in location %u \n”,  y,  &*ptr) ;
    printf (“%u is stored in location %u \n”,  ptr, &ptr) ;
    printf (“%d is stored in location %u \n”,  y,  &y) ;

    *ptr = 25;
    printf (”\nNow x = %d \n”, x);
}
```

```
Address of x:      3221224908
Address of y:      3221224904
Address of ptr:    3221224900
```

Output:

```
10 is stored in location 3221224908
10 is stored in location 3221224908
10 is stored in location 3221224908
10 is stored in location 3221224908
3221224908 is stored in location 3221224900
10 is stored in location 3221224904

Now x = 25
```

Pointer Expressions

- Like other variables, pointer variables can be used in expressions.
- If p1 and p2 are two pointers, the following statements are valid:

```
sum = *p1 + *p2;
prod = *p1 * *p2;
prod = (*p1) * (*p2);
*p1 = *p1 + 2;
x = *p1 / *p2 + 5;
```

`*p1` can appear on the left hand side

Contd.

- What are allowed in C?
  - Add an integer to a pointer.
  - Subtract an integer from a pointer.
  - Subtract one pointer from another (related).
    - If p1 and p2 are both pointers to the same array, then p2–p1 gives the number of elements between p1 and p2.

- **What are not allowed?**
  - **Add two pointers.**

```
p1 = p1 + p2;
```

  - **Multiply / divide a pointer in an expression.**

```
p1 = p2 / 5;
p1 = p1 - p2 * 10;
```

Scale Factor

- We have seen that an integer value can be added to or subtracted from a pointer variable.

```
int  *p1, *p2;
int  i, j;
:
p1 = p1 + 1;
p2 = p1 + j;
p2++;
p2 = p2 - (i + j);
```

  - In reality, it is not the integer value which is added/subtracted, but rather the *scale factor* times *the value*.

Contd.

Data Type	Scale Factor
char	1
int	4
float	4
double	8

- If p1 is an integer pointer, then

  p1++

  will increment the value of p1 by 4.

- **Note:**
  - The exact scale factor may vary from one machine to another.
  - Can be found out using the `sizeof` function.
  - Syntax:

```
sizeof (data_type)
```

Example: to find the scale factors

```
#include  <stdio.h>
main()
{
  printf (”No. of bytes occupied by int is %d \n”,    sizeof(int));
  printf (”No. of bytes occupied by float is %d \n”,  sizeof(float));
  printf (”No. of bytes occupied by double is %d \n”, sizeof(double));
  printf (”No. of bytes occupied by char is %d \n”,   sizeof(char));
}
```

Output:

```
Number of bytes occupied by int is  4
Number of bytes occupied by float is  4
Number of bytes occupied by double is  8
Number of bytes occupied by char is  1
```

Passing Pointers to a Function

- **Pointers are often passed to a function as arguments.**
  - **Allows data items within the calling program to be accessed by the function, altered, and then returned to the calling program in altered form.**
  - **Called *call-by-reference* (or by *address* or by *location*).**
- **Normally, arguments are passed to a function *by value*.**
  - **The data items are copied to the function.**
  - **Changes are not reflected in the calling program.**

Example: passing arguments by value

```
#include  <stdio.h>
main()
{
    int  a, b;
    a = 5;  b = 20;
    swap (a, b);
    printf ("\n a=%d, b=%d", a, b);
}

void  swap (int x, int y)
{
    int  t;
    t = x;
    x = y;
    y = t;
}
```

Output

```
a=5, b=20
```

Example: passing arguments by reference

```
#include  <stdio.h>
main()
{
    int  a, b;
    a = 5;  b = 20;
    swap (&a, &b);
    printf ("\n a=%d, b=%d", a, b);
}

void swap (int *x, int *y)
{
    int  t;
    t = *x;
    *x = *y;
    *y = t;
}
```

Output

```
a=20, b=5
```

scanf Revisited

```
int x, y;
printf ("%d %d %d", x, y, x+y);
```

- What about scanf ?

```
scanf ("%d %d %d", x, y, x+y) ;
```

NO

```
scanf ("%d %d", &x, &y) ;
```

YES

Example: Sort 3 integers

Three-step algorithm:

1. Read in three integers x, y and z
2. Put smallest in x
   - Swap x, y if necessary; then swap x, z if necessary.
3. Put second smallest in y
   - Swap y, z if necessary.

Contd.

```
#include  <stdio.h>
main()
{
     int  x, y, z;
     ……
     scanf (”%d %d %d”, &x, &y, &z);
     if   (x > y)   swap(&x,&y);
     if   (x > z)   swap(&x,&z);
     if   (y > z)   swap(&y,&z);
     ……
}
```

sort3 as a function

```
#include  <stdio.h>
main()
{
    int  x, y, z;
    ……
    scanf (”%d %d %d”, &x, &y, &z);
    sort3 (&x, &y, &z);
    ……
}

void sort3 (int *xp, int *yp, int *zp)
{
    if (*xp > *yp)  swap (xp, yp);
    if (*xp > *zp)  swap (xp, zp);
    if (*yp > *zp)  swap (yp, zp);
}
```

Contd.

- Why no '&' in swap call?
  - Because xp, yp and zp are already pointers that point to the variables that we want to swap.

Pointers and Arrays

- **When an array is declared,**
  - **The compiler allocates a *base address* and sufficient amount of storage to contain all the elements of the array in contiguous memory locations.**
  - **The *base address* is the location of the first element (*index 0*) of the array.**
  - **The compiler also defines the array name as a *constant pointer* to the first element.**

Example

- **Consider the declaration:**

```
int x[5] = {1, 2, 3, 4, 5};
```

  - **Suppose that the base address of x is 2500, and each integer requires 4 bytes.**

Element	Value	Address
x[0]	1	2500
x[1]	2	2504
x[2]	3	2508
x[3]	4	2512
x[4]	5	2516

Contd.

Both `x` and `&x[0]` have the value `2500`.

`p = x;` and `p = &x[0];` are equivalent.

- We can access successive values of **x** by using `p++` or `p--` to move from one element to another.

- **Relationship between p and x:**

```
p   = &x[0] = 2500
p+1 = &x[1] = 2504
p+2 = &x[2] = 2508
p+3 = &x[3] = 2512
p+4 = &x[4] = 2516
```

*(p+i) gives the value of x[i]

Example: function to find average

```
#include <stdio.h>
main()
{
  int x[100], k, n;

  scanf (”%d”, &n);

  for (k=0; k<n; k++)
     scanf (”%d”, &x[k]);

  printf  (”\nAverage is %f”,
                avg (x, n));
}
```

```
float avg (array, size)
int array[], size;
{
  int  *p, i , sum = 0;

  p = array;

  for (i=0; i<size; i++)
       sum = sum + *(p+i);

  return ((float) sum / size);
}
```

Example with 2-D array

TO BE DISCUSSED LATER

Structures Revisited

- Recall that a structure can be declared as:

```
struct stud {
                int     roll;
                char  dept_code[25];
                float   cgpa;
              };
struct   stud   a, b, c;
```

- And the individual structure elements can be accessed as:

```
a.roll ,  b.roll ,  c.cgpa
```

Arrays of Structures

- We can define an array of structure records as

```
struct stud class[100];
```

- The structure elements of the individual records can be accessed as:

```
class[i].roll
class[20].dept_code
class[k++].cgpa
```

Example :: sort by roll number (bubble sort)

```
#include <stdio.h>
struct stud
{
    int  roll;
    char  dept_code[25];
    float  cgpa;
};

main()
{
  struc  stud  class[100], t;
  int  j, k, n;

  scanf  ("%d", &n);
        /* no. of students */
```

```
for (k=0; k<n; k++)
  scanf ("%d %s %f", &class[k].roll,
                 class[k].dept_code,
                 &class[k].cgpa);
for (j=0; j<n-1; j++)
  for (k=1; k<n-j; k++)
  {
    if (class[k-1].roll >
                    class[k].roll)
    {
       t = class[k-1];
       class[k-1] = class[k];
       class[k] = t;
     }
   }
    <<<< PRINT THE RECORDS >>>>
}
```

Example :: selection sort

```
int min_loc (struct stud x[],
                 int k, int size)
int j, pos;
{
   pos = k;
   for (j=k+1; j<size; j++)
      if (x[j] < x[pos])
         pos = j;
   return pos;
}
```

```
main()
{
  struc  stud  class[100];
  int n;
  …
  selsort (class, n);
  …
```

```
int selsort (struct stud x[],int n)

{
   int k, m;
   for (k=0; k<n-1; k++)
   {
      m = min_loc (x, k, n);
      temp = a[k];
      a[k] = a[m];
      a[m] = temp;
   }
}
```

Arrays within Structures

- C allows the use of arrays as structure members.
- Example:

```
struct stud {
                int   roll;
                char  dept_code[25];
                int   marks[6];
                float cgpa;
            };
struct  stud  class[100];
```

- To access individual marks of students:

```
class[35].marks[4]
class[i].marks[j]
```

Pointers and Structures

- You may recall that the name of an array stands for the address of its *zero-th element*.
  - Also true for the names of arrays of structure variables.
- Consider the declaration:

```
struct stud {
                int   roll;
                char  dept_code[25];
                float cgpa;
              }  class[100],  *ptr ;
```

- The name `class` represents the address of the zero-th element of the structure array.
- `ptr` is a pointer to data objects of the type `struct stud`.

- The assignment

```
ptr = class;
```

  will assign the address of `class[0]` to `ptr`.

- When the pointer `ptr` is incremented by one (`ptr++`) :
  - The value of `ptr` is actually increased by `sizeof(stud)`.
  - It is made to point to the next record.

- Once `ptr` points to a structure variable, the members can be accessed as:

```
ptr -> roll;
ptr -> dept_code;
ptr -> cgpa;
```

  - The symbol "`->`" is called the *arrow* operator.

A Warning

- **When using structure pointers, we should take care of operator precedence.**
  - **Member operator "." has higher precedence than "*".**

    `ptr -> roll` and `(*ptr).roll` mean the same thing.

    `*ptr.roll` will lead to error.

  - **The operator "->" enjoys the highest priority among operators.**

    `++ptr -> roll` will increment roll, not ptr.

    `(++ptr) -> roll` will do the intended thing.

Structures and Functions

- A structure can be passed as argument to a function.
- A function can also return a structure.
- The process shall be illustrated with the help of an example.
  - A function to add two complex numbers.

Example: complex number addition

```
#include <stdio.h>
struct complex {
                    float  re;
                    float  im;
                  };

main()
{
   struct  complex  a, b, c;
   scanf  ("%f %f", &a.re, &a.im);
   scanf  ("%f %f", &b.re, &b.im);
   c  =  add (a, b) ;
   printf  ("\n %f %f", c,re, c.im);
}
```

```
struct complex add (x, y)
struct complex x, y;
{
   struct complex  t;

   t.re = x.re + y.re ;
   t.im = x.im + y.im ;
   return (t) ;
}
```

With typedef

```
#include <stdio.h>
typedef struct {
                    float  re;
                    float  im;
                  } complex;

main()
{
   complex  a, b, c;
   scanf  ("%f %f", &a.re, &a.im);
   scanf  ("%f %f", &b.re, &b.im);
   c  =  add (a, b) ;
   printf  ("\n %f %f", c,re, c.im);
}
```

```
complex add (complex x,
                    complex y)
{
   complex  t;

   t.re = x.re + y.re ;
   t.im = x.im + y.im ;
   return (t) ;
}
```

Example: Alternative way using pointers

```
#include <stdio.h>
typedef struct  {
                    float  re;
                    float  im;
                  } complex;

main()
{
   complex  a, b, c;
   scanf  ("%f %f", &a.re, &a.im);
   scanf  ("%f %f", &b.re, &b.im);
   add (&a, &b, &c) ;
   printf ("\n %f %f", c,re, c.im);
}
```

```
void add (x, y, t)
complex  *x, *y, *t;
{
   t->re = x->re + y->re;
   t->im = x->im + y->im;
}
```
